

API Client ID to **src/util/Spotify.js**, and start the Create React App server.

Remember, your solution may not look exactly like ours. What matters is the functionality of your application and the readability of your overall code.

Congratulations on building a full front-end web app!

Potential new Jamming Features

Now that you've completed Jamming, you can also start to add new features to it. Expanding your project features is a great way to practice building new React components, learning more about interacting with the Spotify API, and maintaining your code as your app becomes more complex.

- Pressing enter triggers a search
- Include preview samples for each track
- Only display songs not currently present in the playlist in the search results
- Add a loading screen while playlist is saving
- Update the access token logic to expire at exactly the right time, instead of setting expiration from when the user initiates their next search
- After user redirect on login, restoring the search term from before the redirect
- Ensure playlist information doesn't get cleared if a user has to refresh their access token
- Provide a way to fetch and see all your existing playlists
